

Virata Retail | Reebok | Build Instructions | Database

Task 1

raw schema

Goal: Set up a new, separate Supabase project for Virata Retail (Reebok), and create a landing zone that captures source data exactly as received, with one table per report and new files appended incrementally over time.

Steps:

1. Create a **completely new Supabase project** dedicated to Virata Retail (Reebok), kept entirely separate from the VS Corp workspace. This ensures the Reebok data, pipeline, and infrastructure remain isolated from the existing retail operations, with their own storage, access, and configuration.
2. Within the new project, create a **raw** schema to hold all incoming source data, kept separate from any cleaned or processed data.
3. Create one table per report, following the agreed naming convention. At present there is a single source report, so create one table: **raw_sap_reebok_sales**. Additional tables will be added as more SAP reports become available (for example inventory or goods received), each following the same convention.
4. Set the table's columns to match the source file exactly as received; original column names and structure, with no renaming or reformatting at this stage. The raw layer is intentionally left untouched to preserve a faithful copy of the source.
5. Build the ingestion process so that each new file uploaded is appended incrementally to its corresponding report table, rather than overwriting existing data or creating a separate table per file. This keeps the schema clean while retaining full history.
6. Add audit columns to every raw table — **uploaded_at**, **uploaded_by**, **source_file_name**, and **ingestion_method** — populated automatically at the time of ingestion. These make it possible to trace exactly which file and upload each record came from. Note that the ingestion_method should be manual since the files will be uploaded.
7. Confirm the pipeline runs end to end via GitHub, reading each uploaded file and loading it into the correct raw table.
8. **Verify:** confirm that uploaded files land in the correct report table, that data is captured accurately and matches the source file, that incremental uploads append correctly without overwriting prior data, and that the audit columns are populated on every row.

Outcome: A new, isolated Supabase project is established for Virata Retail (Reebok), with a raw schema capturing data as intended. The single SAP sales report has its own table receiving incremental uploads, source data is preserved exactly as received, and every record is traceable back to its originating file. This forms the stable foundation that the staging layer will

be built on top of, and the structure is ready to scale as additional SAP reports and stores are onboarded.
